

*Cardiac Disorders :*

Men.—National Duration per 1,000 members—258 weeks.

The highest rate in the rural areas is experienced in Longford—477 weeks, with Louth—474 weeks second highest. High rates are also found in Wexford—469 weeks; Laoighis—428 weeks; and Meath—424 weeks. The lowest rates are in Galway—123 weeks; Dublin—154 weeks; and Mayo—161 weeks.

In the urban areas, Clonmel—386 weeks is highest, Cork—344 weeks being second highest. Wexford—327 weeks is next highest. The lowest rate is in Galway—61 weeks, with Dundalk—123 weeks second lowest.

Single Women.—National Duration per 1,000 members—318 weeks.

The highest rates in the rural areas are found in Meath and Wexford—592 weeks each; Louth—582 weeks; and Laoighis—516 weeks being next in order. The lowest rates are Tipperary—192 weeks; Sligo—226 weeks; and Offaly and Donegal—227 weeks each.

The highest rate in the urban areas is 493 weeks (Wexford). This far exceeds any of the other rates experienced in towns for this illness group, the next highest rate being that for Drogheda—416 weeks, which is 77 weeks per 1,000 lower. The lowest rates in the towns are in Kilkenny—62 weeks and Tralee—74 weeks.

*Microbic :*

Men.—National Duration per 1,000 members—90 weeks.

The rate for this type of illness is much smaller than that of any of the other illnesses on which comment has been made in dealing with the regional distribution. The highest rates are found in Laoighis—208 weeks; Carlow—194 weeks; and Louth—186 weeks, while the lowest are in Galway—45 weeks; Mayo—52 weeks; and Monaghan—57 weeks.

In the towns there are no rates above the national rate, the highest rate being 73 weeks which is found in Dundalk; Limerick—71 weeks is second highest. The lowest rates are in Galway—36 weeks and Sligo—42 weeks.

Single Women.—National Duration per 1,000 members—114 weeks.

This group is not one of the main sources of incapacity for women and the figures are not, therefore, analysed.

*Blood Diseases :*

The analysis of the experience for men has been omitted for the same reason as that given above for the omission of the microbic group for single women.

Single Women.—National Duration per 1,000 members—340 weeks.

Tremendously high rates of incapacity are experienced for this illness the figures generally being second only to those of the rheumatism group. The highest rate is in Westmeath—783 weeks. The next highest are Laoighis—696 weeks; Clare—676 weeks; Kilkenny—648 weeks; Roscommon—634 weeks; and Wexford—622 weeks. The lowest rates are in Waterford—152 weeks and Dublin—189 weeks. In the urban areas very high rates are found in Wexford—638 weeks and Drogheda—615 weeks. The rate for Wexford town is not only the highest for that illness for any area either urban or rural, but it is the highest rate experienced for any illness amongst either men or single women for any of the towns. It is almost six times the lowest rate experienced for this illness for single women—(Dundalk—141 weeks).

In the survey that has been given of the regional experience it will be seen that there are great differences in the illnesses and rate of incapacity in the different areas,

but that certain counties and towns are generally prominent, either in view of their good or adverse experience. There is no doubt that serious differences in the ages of insured persons in the different areas have a great influence over the figures. Other factors are, however, of equal importance. The question of the allocation of a member claiming from any given locality to the real locality from which the illness arises presents a certain amount of difficulty. A country person working in a town, will often return home on falling ill, and it is not always easy to determine whether the change is likely to be permanent or whether it is better to allot the illness to the town or not. It has been necessary, at least in the initial years of the preparation of these illness statistics, to limit the data extracted to suit the requirements of the general system of paying health insurance benefits, and to allow for development along what might be thought the most useful channels of investigation. In particular the figures given for the counties are restricted. It is hoped that when those interested and affected have had an opportunity of studying the results of these investigations that the benefit of their advice and criticism may be made available to the advantage of future reports.

#### OCCUPATIONAL DISTRIBUTION OF ILLNESS.

The mutual effect of occupation and health on one another is a field of study which is capable of tremendous development and deserves more attention than has yet been devoted to it in this country.

The investigation of the incidence of illness amongst insured persons is not at present possible as insured persons are not required to keep the Society informed of the exact nature or classification of the occupation in which they are engaged. The information is supplied on the first application for membership. There are, however, many changes in trade and employment from year to year and it would not be safe to base a census of occupations on the information given by members when first taking up employment.

When a claim is made for sickness or disablement benefit, members are again required to state the nature of their occupation and the name of their employer. The information is not always essential in dealing with the claim and it is not therefore always possible to insist on absolute accuracy or precision in the information given. The greatest difficulty met with in this connection is the description "labourer" which is often used indiscriminately on its own. This has led to a very substantial grouping of claims under this heading. In spite of this a certain amount of comparison is possible and the results obtained are of interest not only in themselves but as a guide to the possibilities of development.

In Tables G and H, Appendix, the essential particulars as regards the occupational distribution of duration and claims are given for the main occupations and the main illnesses. It will be seen that for men the bulk of the claims (53.7 per cent.) is from "general labourers" while for women "domestic servants" are shown as being responsible for the greater part of the claims. A classification of the membership based on the Census (1936) figures for occupation would indicate that not more than 9 per cent. of the men might be classed as "general labourers"—it is obvious, therefore, that the sickness figures are overloaded. For women, the Census (1936) basis suggests that over 40 per cent. of those insurable are domestic servants. Though this gives a closer correspondence with the proportion of claims received than did the men's figures, there is yet not sufficient accuracy shown.

Despite this, it is possible to make a good comparison between the occupations by reference to Table XIII. To construct this Table the total incapacity for each of the occupations was taken as 100 and the proportion due to each of the illnesses calculated accordingly. If each of the occupations had exactly similar effects on those occupied in them then the proportions would be similar for each of the occupation groups. Where there is any change, therefore, in the proportions, the influence of occupational differences may be inferred.

*Men :*

For all occupations combined, rheumatism is the premier cause of incapacity causing 21·8 per cent. of the total duration while respiratory disorders, nervous and mental disorders and cardiac disease come next in importance.

*General Labourers.*—In view of the large proportion of the total incapacity that is attributed to this group the close relationship between the proportion for "all occupations" and for this group is expected. It is noticed that rheumatism (24·6 per cent.), respiratory disorders (13·5 per cent.), and heart disease (11·7 per cent.), take a slightly higher proportion of the total incapacity than is found for all occupations.

*Railway Workers.*—For this group the proportion of rheumatism (26·5 per cent.) and heart disease (13·6 per cent.) is higher than that obtaining for any of the other groups.

*Transport Workers.*—Rheumatism (14·8 per cent.) is the primary illness while respiratory disorders (14·7 per cent.) is next in importance. For this occupation, the proportion of respiratory disorders is higher than that experienced in any of the other occupational groups. The proportion of digestive disorders (9·2 per cent.) is also very high.

*Agricultural Workers.*—Rheumatism (24·9 per cent.), Respiratory Disorders (11·8 per cent.), digestive disorders (9·5 per cent.) and heart disease (9·1 per cent.) are the main causes of incapacity. The proportions both of digestive disorders and of microbial fevers are higher than for any of the other occupations.

*Commercial Workers.*—For this group, which consists principally of shop assistants the proportions are very different from those of the occupations previously mentioned. Nervous disorders (10 per cent.) and tuberculosis (15·5 per cent.) are the main causes of incapacity.

The same two illnesses are the principal sources of incapacity for the communications group and the clerical workers. Amongst the clerical workers the proportion of nervous disorders (24·6 per cent.) and of tuberculosis (16·3 per cent.) is exceedingly high.

Amongst the workers in *Wood and Furniture* the proportion of nervous disorders (14·6 per cent.) is rather high.

For *Metal Workers* there is a high proportion of tuberculosis (14·9 per cent.) and of respiratory disorders (14·1 per cent.).

*Single Women :*

*Domestic Servants.*—As this classification covers the greater portion of the duration of illness experienced it is not surprising to find that the portion of incapacity due to each of the various illnesses corresponds closely to that for all occupations combined—rheumatism, blood diseases, nervous disorders and cardiac diseases being responsible for the greater portion of the incapacity.

For *Commercial Workers* there is a substantial difference in the figures. Tuberculosis (13·5 per cent.) is the premier cause of incapacity with blood diseases (13·2 per cent.), nervous and mental disorders (10·3 per cent.) and digestive disorders (9·5 per cent.) next in importance. Rheumatism is only responsible for 9·3 per cent of the incapacity, or almost half the proportion for all occupations combined.

*Makers of Clothing.*—Tuberculosis (11·4 per cent.) and respiratory disorders

(10·1 per cent.) are prominent for this occupation group being the second and third highest proportion. Rheumatism (12·7 per cent.) is the premier incapacity.

*Personal Service and Entertainments.*—For this group of occupations the proportion of rheumatism (22·5 per cent.) is the highest of any of the occupations shown in the Table. For the other illnesses the proportions bear practically the same relationships to one another as those shown for "all occupations."

*Clerical.*—Tuberculosis (17·1 per cent.) is the premier cause of incapacity and is responsible for a much higher proportion of the total incapacity, than is found in any of the other occupations. Nervous disorders (13·2 per cent.) and digestive disorders (9·9 per cent.) are next in importance. These illnesses are also responsible for a greater proportion of the incapacity in this occupational group than was found in any of the other occupations. Rheumatism (6·4 per cent.) is the least important of the illnesses for this group.

This brief survey of the occupational distribution of illnesses discloses that even with the paucity of information available a certain degree of difference between the illness experienced in the various groups, both men and women, can be traced. The material utilised is not sufficient to allocate responsibility to any particular occupation but the results suggest that this field would well repay more detailed examination not only in the field of statistics but more particularly in the domain of preventive medicine. In examining the figures there are some rather important aspects which should be borne in mind. The first of these is the question of selection of occupation. There is a tendency for those who are delicate to seek those occupations in which they will be sheltered. A person suffering from a weak heart will not, if possible, enter an occupation involving heavy physical labour while a person disposed to tuberculosis will not generally be attracted to an occupation involving exposure to bad weather.

Secondly, the problem of the age distribution arises. The illnesses which arise in each occupation will naturally be affected by the age-grouping of those working in that occupation. In the absence of a special census of the insured persons it is not possible to assess the effects of this factor. There is little doubt that great differences must exist—particularly as between clerical workers and manual workers. The National Health Insurance Acts provide that (with a few exceptions) clerical workers earning not more than £250 per annum and all manual workers, shall be insurable. It is natural enough to expect, therefore, that the insured persons amongst clerical workers, when insurance ceases after £250 per annum is reached, will be generally younger than those amongst the manual occupations whose insurance continues irrespective of the rate of remuneration. These factors have a considerable bearing on the figures for occupations and must be allowed for in dealing with them.

#### GENERAL REMARKS.

We have now reached the conclusion of this report on the statistics of the incapacity amongst insured persons in 1935 and 1936. It will be argued—and it has already been argued in connection with an earlier survey of these figures—that the basis on which the classification of illnesses is constructed might not be sufficiently strong to stand such a building. Without a test check by medical referees of the diagnoses given on the medical certificates received (a course which, though formerly rather difficult, is not now impossible of attainment) it would not be possible absolutely to dispose of this argument. If rheumatism be taken as an example, it is found that the very high proportion of rheumatism experienced is unusual,\* and is not to be found to the same extent in other countries.

\* "Chronic Arthritis"—Dr. J. A. Glover. British Stationery Office.  
Annual Reports of Incapacitating Sickness of Insured Population in Scotland:—Department of Health for Scotland.

In general the total amount of incapacity experienced is rather large but the distribution of this into illnesses and ages and the rates of incapacity found at various ages for the different illnesses appear to bear out the more general assertions about these diseases. In the regional distribution of illness, from which it is anticipated that the greatest utility may be derived, there are a number of unusual features but a number of known factors are also reflected. An example of these may be seen in the high rates found for County Wexford, a county in which, in spite of good social services, adverse health conditions have been indicated from independent sources.

The Society has gone to great trouble to collect, tabulate and analyse these statistics. Through the courtesy of the Hospitals Commission they have been able to make them available for the authorities principally concerned and also for the general public. The Society considers that it is the duty of a national organisation to prepare such figures in so far as is reasonable and possible. But there is a further national duty, which is not in the power of the Society to fulfil. The prevention and cure of disease is a duty that concerns and affects many different bodies and organisations in the country. Statistics of incapacitating sickness are a measure of the need for prevention and cure.

To solve a problem it is first necessary to know what constitutes the problem and what its measure. Statistics reveal the problem but other agencies must meet and solve it. The problem of incapacitating disease, if solved, leads to better health. If this report lends strength or direction to the campaign for health it will have served its purpose.
